### Human Infection With Avian Influenza A(H7N9) Virus

On 14 December 2016, the Health Bureau, Macao Special Administrative Region (SAR) (China) confirmed a case of human infection with avian influenza A(H7N9) virus affecting a 58-year old male.

On 13 December 2016, a batch of poultry (Silkies) from Guangdong province in China was found positive for H7 antigen in a wholesale market in Macao SAR (China) during routine inspection. Following protocol, an epidemiological investigation commenced and two close human contacts of the infected poultry were identified, including a poultry vendor and driver. The poultry vendor discharged the concerned batch of poultry from the truck in the early morning of 13 December.

The vendor was referred to hospital for further investigation. He tested positive for avian influenza A(H7N9) by RT-PCR in three specimens at the public health laboratory. He has not had any influenza-like symptom until now and is under observation and being treated with antiviral at a government hospital.

His wife who also works in the same wholesale market was identified as a close contact of the case. She tested negative and is under observation for the next 10 days.

To date, a total of 807 laboratory-confirmed human cases with avian influenza A (H7N9) virus have been reported through IHR notification since early 2013.

### WHO risk assessment:

Most human cases are exposed to A(H7N9) virus through contact with infected poultry or contaminated environments, including live poultry markets. Since the virus continues to be detected in animals and environments, further human cases can be expected. Although small clusters of human cases with influenza A(H7N9) virus have been reported including those involving healthcare workers, current epidemiological and virological evidence suggests that this virus has not acquired the ability of sustained transmission among humans. Therefore further community level spread is considered unlikely.
